# Considerations for Estimating Electrode Performance in Li-Ion Cells

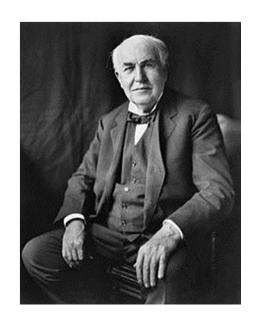

Bill Bennett Electrochemistry Branch May 29-31, 2012

www.nasa.gov

#### Performance estimation

"The storage battery is one of those peculiar things which appeals to the imagination, and no more perfect thing could be desired by stock swindlers than that very selfsame thing.

Just as soon as a man gets working on the secondary battery it brings out his latent capacity for lying."

Thomas Edison Harper's Monthly (1932)

We want to make <u>realistic</u> predictions for battery performance

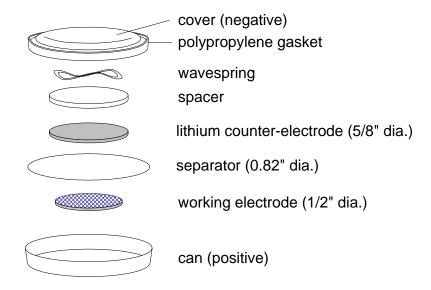

### Li-ion Cell Performance Projections

- Testing of individual electrodes
  - Reversible capacity
  - Irreversible capacity
- Matching electrodes in full cells
- Cell performance estimation Wh/kg

How does electrode performance relate to cell performance?

### Half-cell testing

- Working electrode vs. lithium metal
- Excess negative capacity (> 30x)
- Lithium counter-electrode serves as a pseudo-reference electrode
- Provides data for working electrode capacity and voltage performance

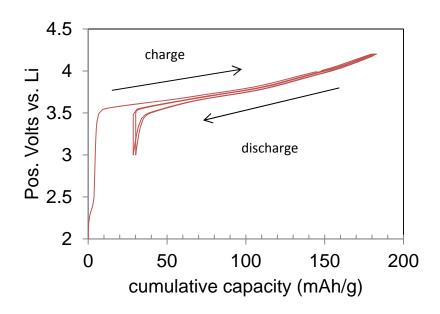

### Half-cell testing – Positive electrode

Cycled to voltage limits

Upper limit: 4.2 V vs. Li

Lower limit: 3.0 V vs. Li

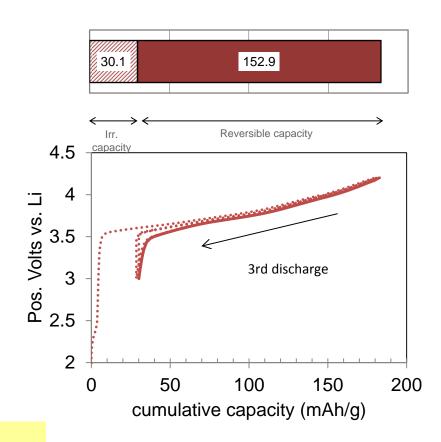

- Capacity per gram of active material in the positive electrode
- Cumulative capacity, running total of charge - discharge
- Data for first three cycles at C/20

### Half-cell testing – Positive electrode

After three cycles:

153 mAh/g reversible capacity30 mAh/g irreversible capacity183 mAh/g total capacity

Based on positive material alone:

153 Ah/kg x 3.7  $V_{avg.} = 566 Wh/kg$ 

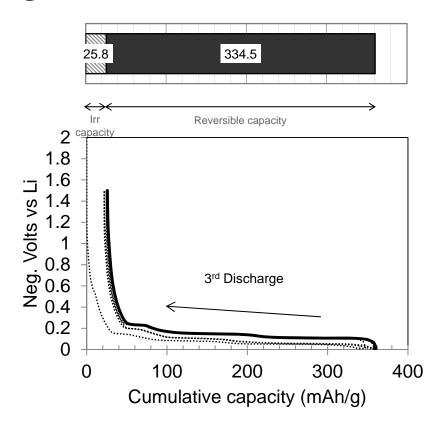

# Half-cell testing – Negative electrode

Cycled to voltage limits

Lower limit: 10 mV vs. Li

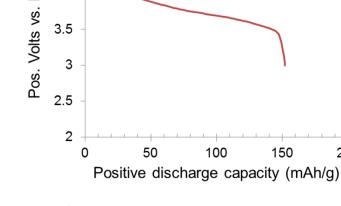

Upper limit: 1.5 V vs. Li

- Capacity per gram of active material in negative electrode
- After three cycles at C/20
   334 mAh/g reversible capacity
   26 mAh/g irreversible capacity
   360 mAh/g total capacity

### Electrode Capacity Summary

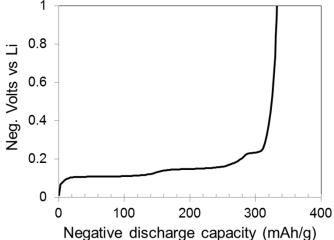

Capacity in mAh/g	positive	negative
Irreversible capacity	30.1	25.8
Reversible capacity _	153.9	334.5
total	183.0	360.3
irreversible capacity as a	19.7%	7.7%
fraction of reversible	13.770	1.1 /0

4.5

4

Let's design a 35 Ah cell using these electrodes.

200

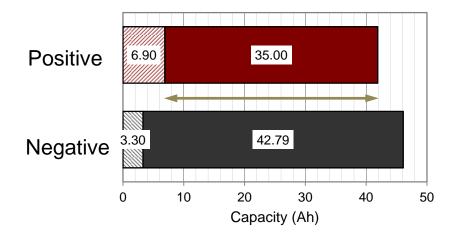

### Design of a 35 Ah Cell

- Choose 35 Ah of reversible positive capacity
- 41.9 Ah of total positive capacity must be accepted by the negative
- Allow 10% excess total negative capacity:

$$110\% \times 41.9 = 46.09 \text{ Ah}$$
  
P/N = 0.909

Negative is not fully utilized

Capacity in Ah	positive	negative
irreversible	6.90	3.30
reversible	35.00	42.79
total	41.90	46.09
irreversible (% of rev.)	19.7%	7.7%

Calculations assume same irreversible capacity as in half-cells

### Design of a 35 Ah Cell

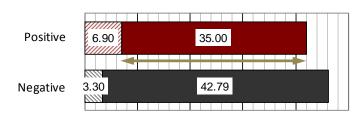

#### Negative electrode utilization

 State-of-charge window for the negative electrode:

90.2% to 8.4% SOC

Positive capacity is fully utilized

Assumes positive irreversible capacity charges the negative to 8.4% SOC

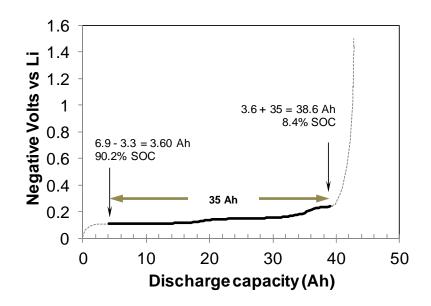

### Prediction of Cell Discharge Voltage

#### Negative electrode

- Assume negative voltage performance as in half-cell
- Delivers 35 Ah between 90.2% to 8.4% SOC
- Projected discharge voltage in bold

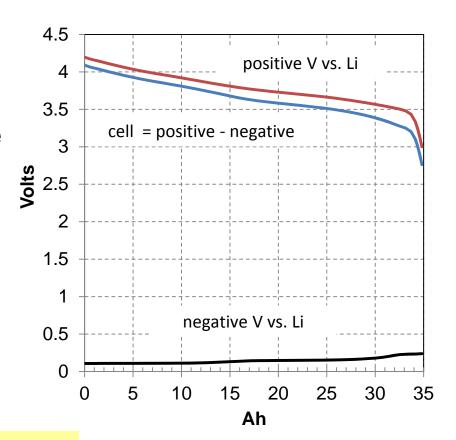

Assumes the partially charged negative has discharge voltage similar to fully charged negative in half-cell.

# Prediction of Cell Discharge Voltage

#### Combined electrode voltage

- Full utilization of positive
- Limited utilization of negative
- Cell voltage by difference
- Projection for low rate (C/20)

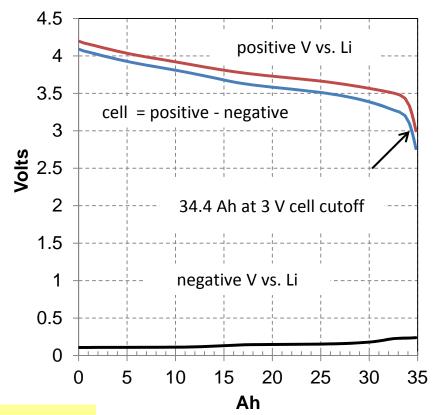

Not applicable to higher discharge rates

### Prediction of Cell Discharge Voltage

#### Projected cell capacity

- Choose 3 V cut-off for cell discharge voltage
- ~34.4 Ah cell capacity

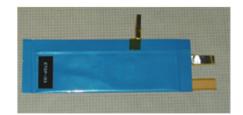

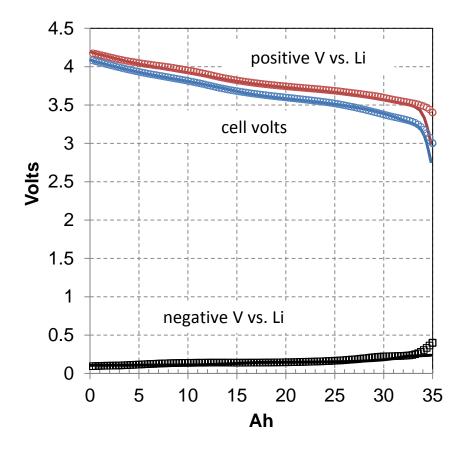

Cell voltage cutoff limits full utilization of the positive electrode capacity

#### Voltage projection vs. full cell data

- Pouch cell with reference electrode, built using same materials as half-cells.
- Reasonable match between data (open symbols) and projections.

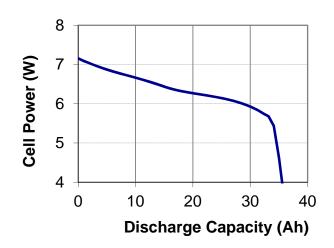

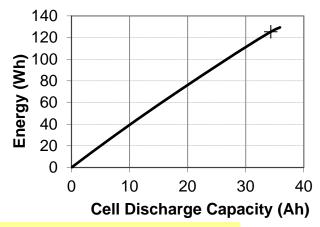

### Discharge Energy Projection

#### **Electrical energy:**

- Calculate power at given current using projected cell voltage
- Integrate power to estimate energy delivered
- 125 Wh at 3 V cutoff

Projected for low discharge rate (C/20 = 1.75 A)

#### **Cell Mass Projection**

#### Cell mass:

- Electrodes = 0.40 kg
- Total material (including electrolyte, separator, current collector) = 0.56 kg
- Allow 18% additional mass for cell case material
- Finished cell = 0.66 kg

positive	negative
35.00	42.79
153.9	334.5
0.227	0.127
86%	97%
0.27	0.13
	35.00 153.9 0.227 86%

Electrodes represent ~60% of the finished cell mass

### Specific Energy Projection

#### Cell-level estimate:

- Energy at C/20 rate to 3 V = 125 Wh
- Finished cell mass = 0.66 kg
- Projected specific energy = 189 Wh/kg

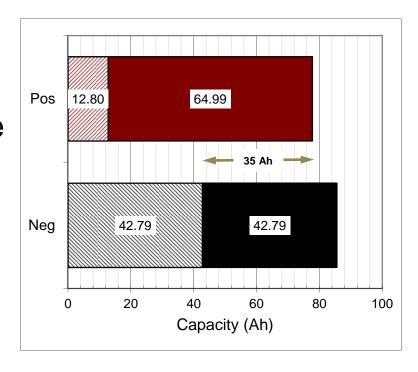

Estimate for a single cell.

Battery-level specific energy would be less!

# Effect of High Irreversible Capacity

35 Ah cell with same positive material.

- 1000 mAh/g negative reversible
- 100% irreversible
- Projected energy = 154 Wh/kg

Un-utilized positive capacity adds significant mass to cell. Erases the benefit to of high negative specific capacity.

### Summary

#### What was shown:

- Capacity considerations (irreversible, reversible, P/N ratio)
- A method to project cell discharge voltage using data for individual electrodes
- Specific energy estimation

Estimates at other rates and temperatures would require half-cell data at the relevant conditions
